WIO Symphony user manual

Manual v 1.0 / Symphony 1.6.0-SNAPSHOT-wio

WIO Symphony stands for *Western Indian Ocean Symphony*. It is a co-developed tool for the assessment of combined – cumulative – environmental impact of different human activities across vast ocean spaces. This open-source tool is useful for marine spatial planning (MSP) and other area based management. The tool is accessible at: www.symphony.nairobiconvention.org

WIO Symphony tutorial

The following tutorial will help you learn how to use the WIO Symphony tool. You may work in small groups, alternating the “driver seat”. The different steps will invite you to discover different parts of the tool. Some tasks can be solved in different ways.

When you have completed the [tutorial](#) you will:

- Be familiar with the tool and its data content.
- Better understand the method and some of the limitations to the tool.
- Have a good idea of the potential of the tool in relation to your own work in marine planning, management or research.

Let’s get started. You should have achieved a personal or organizational [user name](#) and password. Log in as a user at: <https://symphony.nairobiconvention.org>

General

A couple of functions are good to know from start:

- The “eye” symbol use used to visualize data [layers](#), this does not affect the calculations.
- You may always reset everything by refreshing your web browser (press enter). Your completed analyses are saved but everything else is new and fresh.
- The “reset” button in the tool is used to return to default regarding which pressures and ecocomponents are selected for the [analysis](#), and turn all scenario settings (increase/decrease/adding of pressures) back to zero.
- The tool is still Beta version. Some of the layers are insufficient, there might be errors. These will be updated early 2023. If you identify specific errors / inaccuracies in the data layers, please let us know, it might be something we have not yet identified.

Tutorial theme A. Marine Spatial Planning

You work at the *Ministry of Blue Planning* where your team has been tasked to develop MSP solutions based on stakeholder [objectives](#), and analyze different alternatives with respect to environmental impact. You will present your findings to the planning council in the afternoon.

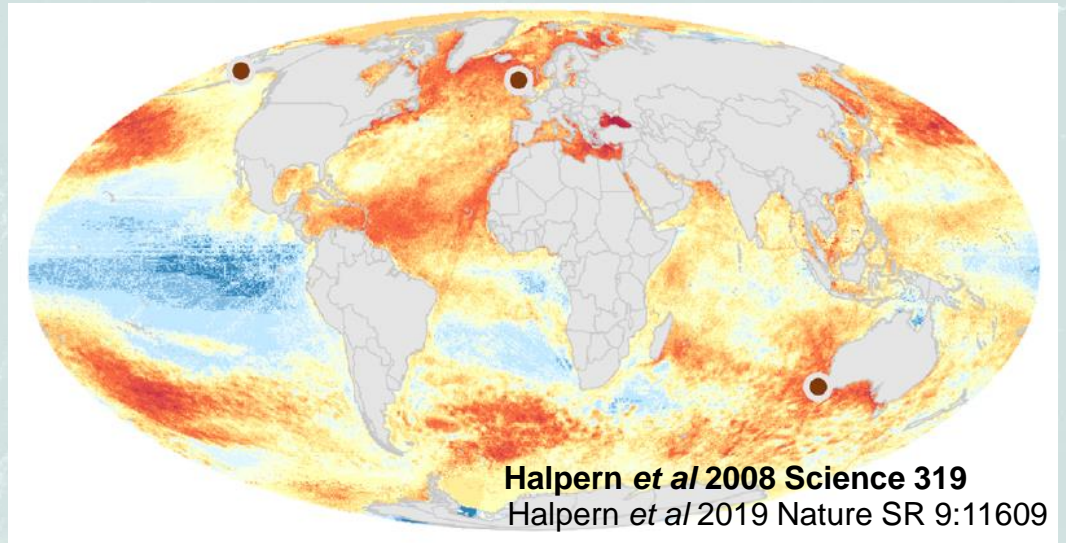

Inventory

1. Browse the ecosystem component list to get an idea of the categories and sorting. A basic difference is Habitat versus Taxa. Habitat is an environment including all its associated organisms. Taxa is a specific species or group. All habitats are pre-selected by default. Another categorization is tropical versus temperate. Each component represents a map. Upwelling areas are nutrient rich habitats often with a lot of sea life. Where in the region do you find upwelling hotspots?

**all models are wrong
some are useful**

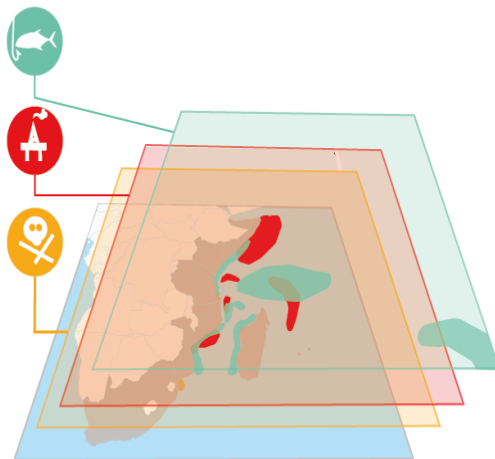

Cumulative impact assessment

Models behind the map

Environmental pressures

From human activities

Ecosystem components

Nature values

Sensitivity matrix

The specific effect of each pressure on each eco-component

Results

Figures and tables

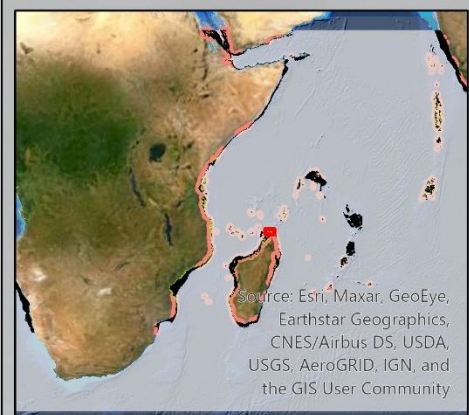

Illustration of coral data processing

Step 8. Uncertainty map

-> Show where coral reefs might occur, but data is missing

- coral uncertainty
- outside range
- very good model
- good model
- no data

Data gaps can lead to underestimated impacts

Swedish Agency
for Marine and
Water Management

Considerations as you put WIO Symphony to work...

1. What can WIO Symphony tool answer? Additional science needed needed for your question?
2. How does data quality & availability effect the analysis
3. How does the sensitivity matrix connect pressures and ecosystems in space and time
